What is Orcus RAT? Technical Analysis and Malware Configuration

Our malware analysts are always on the lookout for and researching various malicious samples. This time we came across Orcus RAT in [ANY.RUN online malware sandbox](#) and decided to perform a technical malware analysis. In this article, you will learn how this RAT stores and protects its configuration and how to write the memory dump extractor in Python.

What is Orcus RAT?

Orcus is a Remote Access Trojan with some distinctive processes. The RAT allows attackers to create plugins and offers a robust core feature set that makes it quite a dangerous malicious program in its class.

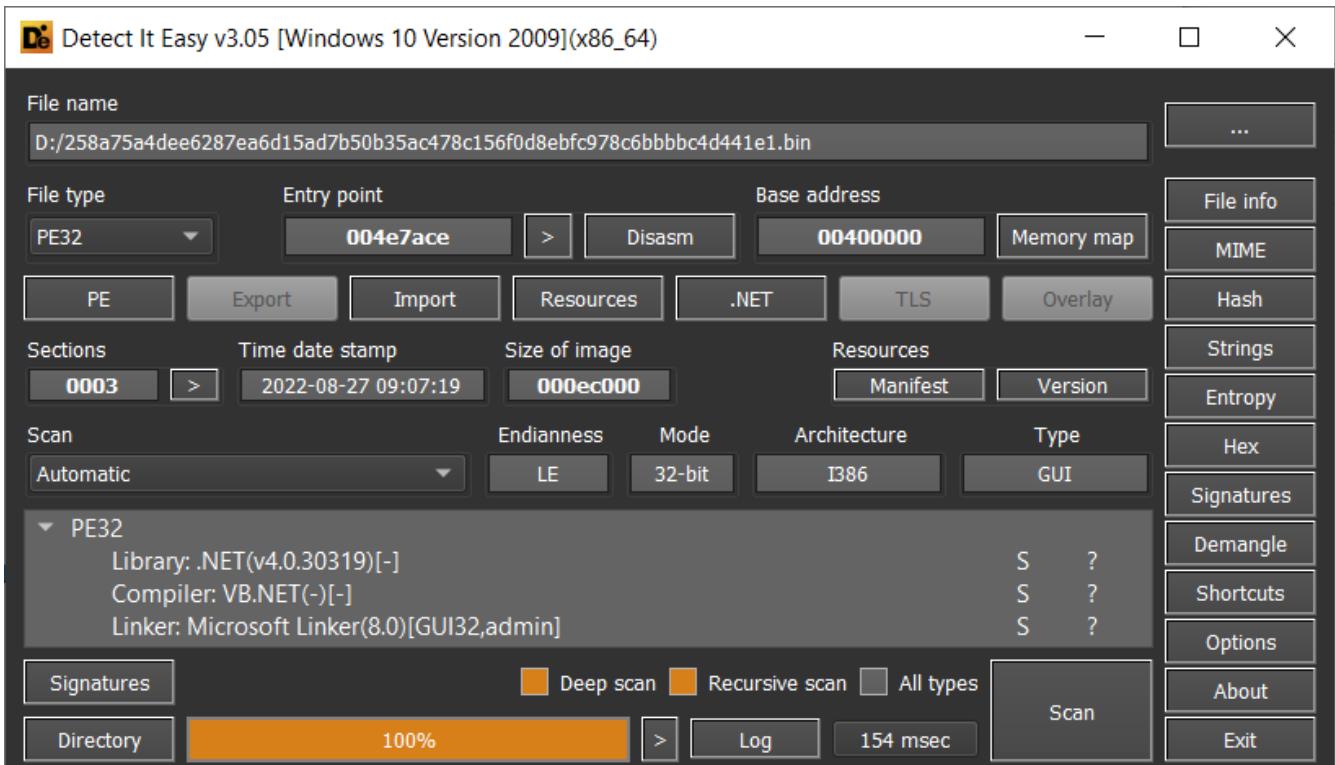

Orcus RAT malware analysis

The sample for the [malware analysis](#) has been obtained from the [ANY.RUN database](#). You can find it and follow along:

SHA-256 258a75a4dee6287ea6d15ad7b50b35ac478c156f0d8ebfc978c6bbbb4d441e1

We downloaded the Orcus RAT sample and opened it in DiE to get basic information:

The DiE results show that we are dealing with a .NET sample. And it's high time to start malware analysis of Orcus. For this matter, DnSpy comes in handy.

```

```

Orcus RAT classes overview

Our primary research goal is to find the RAT configuration. The first destination point is malware classes. While going through them, we bump into a namespace called Orcus.Config, and it contains the following classes:

Consts include information about the different files and directories that Orcus RAT uses. For example, the path to the file where user keystrokes are saved or to the directory where the plugins used by a sample reside.

Assembly Explorer Consts

```

    namespace Orcus.Config
    {
        // Token: 0x020000C3 RID: 195
        internal class Consts : IPathInformation
        {
            // Token: 0x0600027E RID: 638 RVA: 0x0000B90C File Offset: 0x00009B0C
            static Consts()
            {
                string mutex = Settings.GetBuilderProperty<MutexBuilderProperty>().Mutex;
                string path = Settings.GetBuilderProperty<DataFolderBuilderProperty>().Path;
                Consts.KeyLogFile = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("klg_{0}.dat", mutex));
                Consts.ExceptionFile = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("err_{0}.dat", mutex));
                Consts.PluginsDirectory = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("ptc_{0}", mutex));
                Consts.FileTransferTempDirectory = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("psb_{0}", mutex));
                Consts.PotentialCommandsDirectory = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("ptc_{0}", mutex));
                Consts.StaticCommandPluginsDirectory = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("stc_{0}", mutex));
                Consts.SendToServerPackages = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("sts_{0}", mutex));
                Consts.LibrariesDirectory = Path.Combine(Environment.ExpandEnvironmentVariables(path), string.Format("lib_{0}", mutex));
                Consts.ApplicationPath = Application.ExecutablePath;
            }
        }
    }

```

Settings contain wrapper methods for decrypting the malware configuration and its plugins.

Assembly Explorer Settings

```

    namespace Orcus.Config
    {
        // Token: 0x020000C4 RID: 196
        public static class Settings
        {
            // Token: 0x06000292 RID: 658 RVA: 0x0000BAAB File Offset: 0x00009CAB
            static Settings()
            {
                string decryptedSettings = Settings.GetDecryptedSettings();
                XmlSerializer xmlSerializer = new XmlSerializer(typeof(ClientConfig), BuilderPropertyHelper.GetAllBuilderPropertyTypes());
                using (StringReader stringReader = new StringReader(decryptedSettings))
                {
                    Settings.ClientConfig = (ClientConfig)xmlSerializer.Deserialize(stringReader);
                }
            }
        }
    }

```

SettingsData is a static class only with the encrypted malware and plugin configuration fields.

Assembly Explorer SettingsData

```

    namespace Orcus.Config
    {
        // Token: 0x020000C2 RID: 194
        public static class SettingsData
        {
            // Token: 0x0600027D RID: 1204
            static string SETTINGS = "3E05516w+ete9/Th093gIwB2A7wpLw1n90Fw5ccxmB6wLaZnSd1m/LvTqk2jqfcfM37l+CaI071nA5wSIffjyQaVL7cEE59P9yZIk+68wC5iGjgVh9e17zWf1BAnjP0Nigb9vE+6tVdIdyW3PeF2GVFX0+RsKCTtK9add0rHwvbwMpCK9hd097MytVF87wD/IUjcz1n4cpMsJ0z3k9s/F8rJH6GmkaE7mTFSKEckIpX+MzTPdettWig0z2rFCCl08bkJw7t08bbYz7BCvnBNAtNrC/s5l3fts1d05joNGtFYhAzt1SsgIAQ14nDx3Ba2f7c7My+Rq651Xjh2GtFjRFBwMgETTVp19GR+Ewv0XXZm01gdqyru6j6U2yWfd+jtGQqr+gu8z+eFvhjbh3REzohXsK1Gnac/H+HtJa7:f1SwkThc0w0611Zp/e6y4FF+/quJqZGEmnXIUbwobPa3TrOe9T1yBmpUhlp84+dEp60ysXk9D1Cqfb6g0pVS1M00h0p0fcrh165DX050Bg9vJwQeR7He/r8wEj+31ElbDphb9vCrqvis1xtqtkzjpy061pb9rfzaA111Xv5C81frf53YR71shdhYwkuq+awfpgYu/P6bdok53qmW/f4+b0fQfCzxx+z2FKFoXnHc+Cw/bGdHALXvxeXb-Ep0cmkzth2oEwmk1KtVh1bGoxUlbw0vFdxT7sem9ccby3LjMrv0/A3c7R7oxM/SyfFxKs/G74iaK5Fkx8D9w+fTOMpH05718e5H85TFeGyTJEw8ZvapjgX438D15WpnYJds0ZYwes16PrPftmr8UsZgeEi1Uv1hKY2u0CaasRoyTwSLdzHw3nfgrhaCX74CC30Ke219eNI23FzYgst09+b8+lyvC76AP7X3vEw-D5XhG0gLvxts53nSM/4eryChrH65GhHeaC075H8BdCMV726Tf0v7yBfyt/r0ggF/vz1E06GGK9C112yZ/g55ygibEMH0MML+3dyvB8R5rg6gi0wLd85s3uhxLisXk1afbf/oxzjgnz2kpFvCKEub0gnrz11JfodGz+jutB4j1yIG72gj9QhP9gWokSr40ZbeP1l+mgIxanHrgg1Buqx0BwQvvhxvqvhYR63Hmk131Yaq17jad4hZK1N0yJhpb85m9H085s+HnJumkmw0270z90h660aXSwMgpLMTWst3Rg1eG51m:GNXAZIUcILAhyGf4W+pdin5AnYObnvCaYSNChdCsj0AOg9Yhpb85m9H085s+Lj0085g9hLqzzmlJ0q188/gjicz<c>+reInAFxF1p082VgEohBqbeukWfHxsZxcv3/dugo!Sge+83RCb/Dl07vvZ2wtm09;seM8J0efzLz1d35afCLjToV1NMq5Mdz0R2yztz4ouxm3n14kskuTh16rhB8gyAlMaK/z2j+ndikfksa8NcVbos21MWjJzbxsmCk1LM1fsprUtmH2Khzuk26PHuajolegvEmrsJyjuP+14Mfqf17GuNber0e19157tghzIj1r5BZYAUpp10B3+TOX7V9SYkgIMZXYAY11LQmca1w1nBSELKdvGOLg62Ncf0teHpw9EW2dcHxg3UqcNHjsj9ehZsg42XgNgntCmD1UDHTpDiyYw+o8wnhBxurhXkXkgIiUm21B129d1059KTGia+3Typtj1cInh0x28/qASElctEDWn19p5vrs+bsP80UqLfxW88cj+kVMD20A29yvWhrxX9CKVH2F4H1ElycofDM-Bw1j1x8xPm33fRTNqX410shgkUTjCkeodmM54uej31S4LYz1TN4cuz1p1UJvma65zf1sk>3TigCb6tVhQ3C7s+Nkk0LoA11lnf55rs>+1BsHIjP2mQc9gy5/cxzCca5VG7z8d0T66nL9NCvva1wVg1QEuKireKapD5imc5MsD721eC2y5xw7PV+LcWhkVLjFmo7rxkvr+skwfz

```

Orcus malware resources

Inside the **Settings** class, we see the **GetDecryptedSettings** method. Later, it calls out the **AES.Decrypt**. After noticing it, we can suppose that the AES algorithm encrypts the malware configuration:

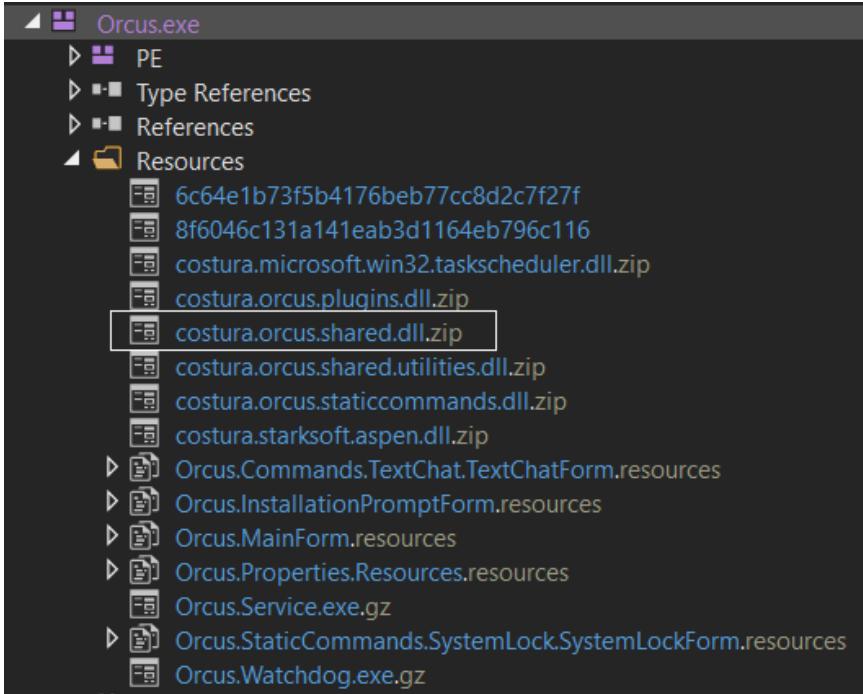

GetDecryptedSettings() : string X

```

    1 // Orcus.Config.Settings
    2 // Token: 0x06000297 RID: 663 RVA: 0x0000BBEC File Offset: 0x00009DEC
    3 public static string GetDecryptedSettings()
    4 {
    5     return AES.Decrypt(SettingsData.SETTINGS, SettingsData.SIGNATURE);
    6 }

```

The **AES** class is imported from the **Orcus.Shared.Encryption**. The only problem is that the assembly doesn't contain such a namespace. To find it, we can go to the Orcus RAT resources:

We seem to have found an assembly **orcus.shared**. But what is this **costura** prefix? And why is the assembly stored with a .zip extension? We extracted this resource and tried to unpack it. Unfortunately, it was a miss – despite the .zip extension, this resource is not an archive.

Realizing that, at some point, this assembly must be loaded into the application, we make a decision to look for another place where this happens. Of course, keeping that strange costura prefix in mind. And it didn't take us long – we have found the **Costura** namespace that contains the **AssemblyLoader** class. It is supposed to load the assemblies packed in Orcus resources.

The screenshot shows the Visual Studio interface with the Assembly Explorer on the left and the code editor on the right. The Assembly Explorer shows the 'Costura' namespace, specifically the 'AssemblyLoader' class. The code editor displays the C# code for the 'AssemblyLoader' class, which includes methods for loading assemblies from various streams and dictionaries.

```

Assembly Explorer

    ▾ {} Orcus.Commands.ClipboardManager

AssemblyLoader
143 // Token: 0x0600086B RID: 2155 RVA: 0x0002B848 File Offset: 0x00029A48
144 // Note: this type is marked as 'beforefieldinit'.
145 static AssemblyLoader()
146 {
147     AssemblyLoader.assemblyNames.Add("microsoft.win32.taskscheduler", "costura.microsoft.win32.taskscheduler.dll.zip");
148     AssemblyLoader.assemblyNames.Add("orcus.plugins", "costura.orcus.plugins.dll.zip");
149     AssemblyLoader.assemblyNames.Add("orcus.shared", "costura.orcus.shared.dll.zip");
150     AssemblyLoader.assemblyNames.Add("orcus.shared.utilities", "costura.orcus.shared.utilities.dll.zip");
151     AssemblyLoader.assemblyNames.Add("orcus.staticcommands", "costura.orcus.staticcommands.dll.zip");
152     AssemblyLoader.assemblyNames.Add("starksoft.asp", "costura.starksoft.asp.dll.zip");
153 }
154
155
156 // Token: 0x0600086C RID: 2156 RVA: 0x0002B8EC File Offset: 0x00029AEC
157 private static Assembly <Attach>b__0(object s, ResolveEventArgs e)
158 {
159     return AssemblyLoader.ResolveAssembly(e.Name);
160 }
161
162 // Token: 0x0600086D RID: 2157 RVA: 0x0002B8FC File Offset: 0x00029AF0
163 public static void Attach()
164 {
165     AppDomain currentDomain = AppDomain.CurrentDomain;
166     currentDomain.AssemblyResolve += ((object s, ResolveEventArgs e) => AssemblyLoader.ResolveAssembly(e.Name));
167 }
168
169 // Token: 0x040008D6 RID: 2262
170 private static readonly Dictionary<string, bool> nullCache = new Dictionary<string, bool>();
171

```

Inside the **AssemblyLoader** class, we have caught how assemblies are loaded from resources:

```

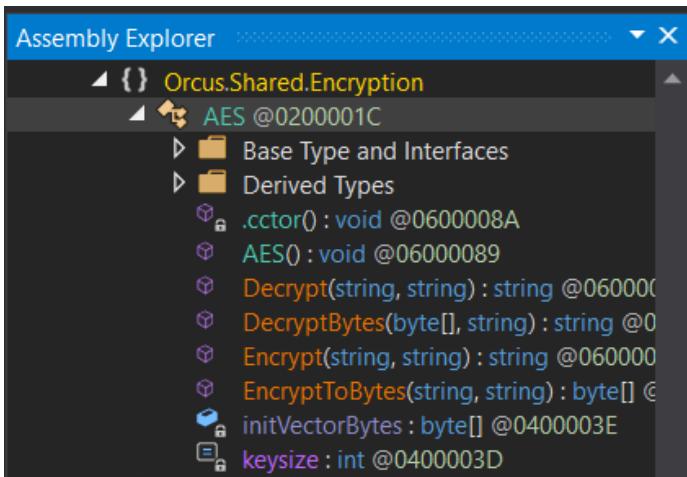

// Costura.AssemblyLoader
// Token: 0x06000866 RID: 2150 RVA: 0x0002B658 File Offset: 0x00029858
private static Stream LoadStream(string fullname)
{
    Assembly executingAssembly = Assembly.GetExecutingAssembly();
    if (fullname.EndsWith(".zip"))
    {
        using (Stream manifestResourceStream = executingAssembly.GetManifestResourceStream(fullname))
        {
            using (DeflateStream deflateStream = new DeflateStream(manifestResourceStream, CompressionMode.Decompress))
            {
                MemoryStream memoryStream = new MemoryStream();
                AssemblyLoader.CopyTo(deflateStream, memoryStream);
                memoryStream.Position = 0L;
                return memoryStream;
            }
        }
    }
    return executingAssembly.GetManifestResourceStream(fullname);
}

```

After repeating this operation with [CyberChef](#), we got an unpacked assembly.

The screenshot shows the CyberChef interface with the 'Raw Inflate' recipe selected. In the 'Input' section, a file named 'costura.orcus.shared.dll.zip' is loaded, showing its details: Name: costura.orcus.shared.dll.zip, Size: 160 967 bytes, Type: application/zip, and Loaded: 100%. The 'Output' section displays the raw assembly code of the unpacked executable, starting with the MZ header and followed by various sections like .text, .rsrc, and .data. At the bottom, there is a green button labeled 'BAKE!' with a chef icon, and a checked checkbox for 'Auto Bake'.

To avoid any second thoughts, we upload the unpacked assembly to DnSpy. Hopefully, it can confirm or deny our assumption about the encryption algorithm used by the Orcus RAT.

This class contains methods for encrypting and decrypting data, as well as an initialization vector field for the AES algorithm and a field with the key length. We are not really interested in the **encryption** process, but the data **decryption** is exactly what we need:

```
public static string Decrypt(string cipherText, string passPhrase)
{
    if (string.IsNullOrEmpty(cipherText))
    {
        return string.Empty;
    }
    return AES.DecryptBytes(Convert.FromBase64String(cipherText), passPhrase);
}
public static string DecryptBytes(byte[] cipherText, string passPhrase)
{
    byte[] bytes = new PasswordDeriveBytes(passPhrase, null).GetBytes(32);
    string @string;
    using (RijndaelManaged rijndaelManaged = new RijndaelManaged())
    {
        rijndaelManaged.Mode = CipherMode.CBC;
        using (ICryptoTransform cryptoTransform = rijndaelManaged.CreateDecryptor(bytes, AES.initVectorBytes))
        {
            using (MemoryStream memoryStream = new MemoryStream(cipherText))
            {
                using (CryptoStream cryptoStream = new CryptoStream(memoryStream, cryptoTransform, CryptoStreamMode.Read))
                {
                    byte[] array = new byte[cipherText.Length];
                    int count = cryptoStream.Read(array, 0, array.Length);
                    @string = Encoding.UTF8.GetString(array, 0, count);
                }
            }
        }
    }
    return @string;
}
```

Orcus RAT data decryption

We have found out the following information concerning data decryption:

1. **Base64** is applied to the encrypted data besides the AES algorithm.
2. The exact encryption type is AES256-CBC.
3. We identified how the encryption key is derived.

Let's discuss this stage, this one is definitely interesting. To generate the key for a given string, Orcus uses the **PasswordDeriveBytes** class, which is based on the **PBKDF1** algorithm from Microsoft. The malware uses the default settings: it means that the number of iterations for key generation will be 100, and the hashing algorithm will be **SHA1**.

```
public PasswordDeriveBytes(string strPassword, byte[]? rgbSalt, CspParameters? cspParams) :
    this(strPassword, rgbSalt, "SHA1", 100, cspParams) { }
```

Are you wondering how it's done? Here is a scenario:

The first 20 bytes proceed as usual, then a byte counter is added to each hashed byte of the inherited string from the 20th to the last byte. Taking it into account, we implemented this in Python:

```
# microsoft's pbkdf1 implementation
def __pbkdf1(self, password, salt, count=32, iterations=100) -> bytes:
    def do_hash(data) -> bytes:
        _sha1 = hashlib.sha1()
        _sha1.update(data)
        data = _sha1.digest()
        return data

    if len(salt) > 0:
        password = password + salt

    for i in range(iterations - 1):
        password = do_hash(password)

    ret = do_hash(password)

    i = 1
    while len(ret) < count:
        ret += do_hash(bytes(str(i), encoding="ascii") + password)
        i += 1

    return ret[:count]
```

Knowing the correct key, you can decrypt the data using [CyberChef](#).

The screenshot shows the CyberChef interface with the following details:

- Recipe:** From Base64
- Input:** The base64-encoded malware configuration: 30E5516w+ete9/T0h93gIwW2A7VpLwX1n90Fw5cxxcmB6wLaZnSdlm/LvTqk2jqfcmt37l+CaI071mA5wSIfhfjy6AqvwL7CE... (length: 15384, lines: 1)
- Decoding Options:**
 - Alphabet: A-Za-z0-9=/
 - Remove non-alphabet chars (checked)
 - Strict mode (unchecked)
- AES Decrypt:**
 - Key: 415434738C1FFA7635528C8D77E07A8544F78... (HEX)
 - IV: 0sjufcjbsoyzube6 (UTF8)
 - Mode: CBC
 - Input: Raw
 - Output: Raw
- Output:** The decrypted XML configuration (length: 11523, lines: 292).

```
<?xml version="1.0" encoding="utf-16"?>
<ClientConfig xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <PluginResources>
    <PluginResourceInfo>
      <ResourceName>6c64e1b73f5b4176beb77cc8d2c7f27f</ResourceName>
      <ResourceType>ClientPlugin</ResourceType>
      <Guid>dccb1db-f7d1-413d-bba4-72611d485d3a</Guid>
      <PluginName>BSOD Protection</PluginName>
      <PluginVersion>2.0</PluginVersion>
    </PluginResourceInfo>
    <PluginResourceInfo>
      <ResourceName>8f6046c131a141eb3d1164eb796c116</ResourceName>
      <ResourceType>ClientPlugin</ResourceType>
      <Guid>e6ee5674-bb94-46c7-8bbc-5729af6e2c28</Guid>
```

Buttons at the bottom:

- STEP
- BAKE! (highlighted in green)
- Auto Bake

As a result of decoding, we get the malware configuration in the XML format.

The screenshot shows the XML Tree viewer interface. The path in the title bar is: ...ject ▶ ClientConfig ▶ Settings ▶ ClientSetting ▶ 5 ▶ Properties ▶ PropertyNameValue ▶ Name. The tree view displays the following structure:

```

    ▼ clientSetting [22]
        ► 0 {2}
        ► 1 {2}
        ► 2 {2}
        ► 3 {2}
        ► 4 {2}
        ▼ 5 {2}
            ▼ Properties {1}
                ▼ PropertyValue {2}
                    Name : IpAddresses

```

Automating the configuration extraction process of Orcus RAT

Now, we will write a Python script with the necessary data to decrypt and automate the configuration extraction. After studying some samples, we have seen that the strings with the encrypted data are located one after another in the UserString stream between two other specific UserString objects (the strings “caseFromAdministrationPackage.GetScreen” and “klg_”).

Next, using the **dnfile** library, we implement a simple algorithm that iterates through the UserStrings looking for the strings mentioned above. And it's important to note that the number of received strings between them must be three:

1. The main encrypted configuration of malware
2. The encrypted configuration of the plugins that Orcus uses
3. The key from which the AES key will be generated

```

cfg_data = []
should_collect_data = False
us: dnfile.stream.UserStringHeap = dn.net.metadata.streams.get(b"#US", None)

if us:
    size = us.sizeof() # get the size of the stream
    offset = 1 # the first entry (the first byte in the stream) is an empty string, so skip it

    while offset < size: # while there is still data in the stream
        # read the raw string bytes, and provide the number of bytes to read (includes the encoded length)
        ret = us.get_with_size(offset)
        if ret is None:
            break

        buf, readlen = ret

        try:
            s = dnfile.stream.UserString(buf) # convert data to a UserString object

            if "klg_" in s.value: break # hit an encapsulating string, leaving..

            if should_collect_data: # collect everything between reference strings
                cfg_data.append(s.value)

            if s.value == "case FromAdministrationPackage.GetScreen":
                should_collect_data = True # we should collect data starting from this line

        except UnicodeDecodeError:
            raise ValueError(f"Bad string: {buf}")

        offset += readlen # continue to the next entry

if len(cfg_data) != 3:
    raise ValueError("Got invalid cfg data")

return cfg_data

```

You can also always use [ANY.RUN](#) service to automatically retrieve the Orcus RAT configuration. It's a much easier way to analyze a malicious object in a short period of time. For example, the sandbox has already retrieved all data from this [Orcus sample](#), so you can enjoy smooth research.

Malware configuration

Here are the details of the configuration

PID 640 X

Orcus (1)

Hide all Copy selected (0) Download JSON

Orcus is a modular Remote Access Trojan with some unusual functions. This RAT enables attackers to create plugins using a custom development library and offers a robust core feature set that makes it one of the most dangerous malicious programs in its class.

Conclusion

In this article, we briefly analyzed the Orcus RAT and automated its configuration extraction. The [full version of the extractor](#) is available at the link, so don't forget to check it out!

Orcus has become another chapter in our malware analysis series. Read our previous posts about [STRRAT](#) and [Raccoon Stealer](#). What should we cover next?

The post blitz survey

What is Orcus RAT?

Orcus is a Remote Access Trojan that allows attackers to create plugins and offers a robust core feature.

Where and how does Orcus store additional assemblies?

Orcus RAT stores additional assemblies inside the the malware resources using a 'deflate' algorithm.

How does Orcus encrypt data?

Orcus RAT encrypts data using the AES algorithm and then encodes encrypted data using Base64.

How can we decrypt Orcus RAT?

First, you need to generate the key from a given string using Microsoft's PBKDF1 implementation. Second, decode the data from Base64. Finally, apply the generated key to decrypt the data via the AES256 algorithm in CBC mode. As a result of decoding, we get the malware configuration in the XML format.
